(57) **ABSTRACT**

Embodiments include a method of disseminating informa-
tion regarding at least one electrical device using a regis-
tration server. The at least one electrical device has unique
identification information, an internal IP address, and an
external IP address, wherein the external IP address is an IP
address of a first gateway device for a first local network.
The method can include: receiving in the registration server
a first request to register the at least one electrical device, the
first request to register includes the unique identification
information, the internal IP address, and the external IP
address of the at least one electrical device; storing in the
registration server the unique identification information, the
internal IP address, and the external IP address of the at least
one electrical device using the registration server; receiving
in the registration server from a first client computer a first
request for information regarding the at least one electrical
device, the first request includes the external IP address of
the first client computer and the unique identification infor-
mation of the at least one electrical device; providing to the
first client computer the external IP address of the at least
one electrical device if the external IP address of the first
client computer is different from the external IP address of
the at least one electrical device; and providing to the first
client computer the internal IP address of the at least one
electrical device if the external IP address of the first client
computer is identical to the external IP address of the at least
one electrical device. The registration server is not part of
the first local network. In some examples, the at least one
electrical device and the first gateway device are part of the
first local network. Other embodiments are disclosed.

METHOD OF DISTRIBUTING INFORMATION REGARDING ONE OR MORE ELECTRICAL DEVICES AND SYSTEM FOR THE SAME

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a divisional application of U.S. patent application Ser. No. 13/077,782, filed Mar. 31, 2011. U.S. patent application Ser. No. 13/077,782 is incorporated herein by reference in its entirety.

FIELD OF THE INVENTION

This invention relates generally to systems and method to provide information, and relates more particularly to systems configured to provide information regarding electrical devices and methods for the same.

DESCRIPTION OF THE BACKGROUND

In today's widely used IP (internet protocol) networks, the Dynamic Host Configuration Protocol (DHCP) is commonly used to dynamically assign an IP address to an electrical device coupled to a network. DHCP is a useful and convenient mechanism that allows new electrical devices to connect to a network without manual configuration. Although DHCP allows the assignment of a dynamic IP address to an electrical device, no convenient method exists for other electrical devices or users to determine the new dynamically assigned IP address of the electrical device. Because the IP address has been dynamically assigned, the IP address can change every time the electrical device is plugged into the network, removed, and plugged in again so the dynamically assigned IP address of the electrical device may need to be repeatedly determined.

Many methods to retrieve the dynamically assigned IP address involve using proprietary visual user interfaces of the electrical device or a gateway device. For example, if the electrical device has a visual display capability (e.g., laptops, mobile phones, printers with an LCD display, game consoles coupled to a television, etc.), a proprietary method of navigating a visual user interface usually exists to allow the user to determine the new dynamically assigned IP address.

In the same or different examples, the router or other gateway device that hosts the DHCP server can have a proprietary visual user interface that allows the user to navigate a series of screens, menu items, and/or commands to determine the newly assigned dynamic IP address for the electrical device. However, in this method, the user is required to know the MAC (media access control, or hardware) address of the electrical device and then look up the MAC address in a table to find the associated dynamically assigned IP address.

Furthermore, standard and widely adopted protocols such as UPnP (universal plug and play), DLNA (digital living network alliance), and Bonjour work in the application layer above TCP/IP (transmission control protocol/internet protocol) and allow for dynamic discovery of new electrical devices provided that those new electrical devices also participate in and support the proprietary discovery protocol. However, these protocols are generally only useful within a local private network. If the proprietary discovery protocol works in both private and public networks, the proprietary discovery protocol requires the user to enter two different

2

addresses to access the electrical device depending on whether the user is inside or outside of the local network.

Accordingly, a need or potential for benefit exists for a method and/or system that allow a user to discover easily a dynamically assigned IP address for an electrical device and to access and use the electrical device without knowing the DHCP address.

BRIEF DESCRIPTION OF THE DRAWINGS

To facilitate further description of the embodiments, the following drawings are provided in which:

FIG. 1 illustrates a block diagram of a system configured to provide information regarding at least one electrical device, according to a first embodiment;

FIG. 2 illustrates a block diagram of an exemplary electrical device of FIG. 1, according to the first embodiment;

FIG. 3 illustrates a rear view of an exemplary gateway device of FIG. 1, according to the first embodiment;

FIG. 4 illustrates a representative block diagram of an example of the elements included in the circuit boards inside a chassis of the gateway device of FIG. 3;

FIG. 5 illustrates a front view of an exemplary internal client computer of FIG. 1, according to the first embodiment;

FIG. 6 illustrates a representative block diagram of an example of the elements included in the circuit boards inside a chassis of the internal client computer of FIG. 5;

FIG. 7 illustrates a block diagram of an exemplary registration server of FIG. 1, according to the first embodiment;

FIG. 8 illustrates a flow chart for an exemplary embodiment of a method of distributing information regarding one or more electrical devices using a first server, according to the first embodiment;

FIG. 9 illustrates a flow chart for an exemplary embodiment of an activity of registering the electrical device, according to the first embodiment;

FIG. 10 illustrates a flow chart for an exemplary embodiment of an activity of processing a request for information about the electrical device, according to the first embodiment;

FIG. 11 illustrates a flow chart for an exemplary embodiment of a procedure of authenticating a user of the client computer, according to the first embodiment; and

FIG. 12 illustrates a flow chart for an exemplary embodiment of a procedure of providing the requested information about the electrical device, according to the first embodiment.

For simplicity and clarity of illustration, the drawing figures illustrate the general manner of construction, and descriptions and details of well-known features and techniques may be omitted to avoid unnecessarily obscuring the invention. Additionally, elements in the drawing figures are not necessarily drawn to scale. For example, the dimensions of some of the elements in the figures may be exaggerated relative to other elements to help improve understanding of embodiments of the present invention. The same reference numerals in different figures denote the same elements.

The terms "first," "second," "third," "fourth," and the like in the description and in the claims, if any, are used for distinguishing between similar elements and not necessarily for describing a particular sequential or chronological order. It is to be understood that the terms so used are interchangeable under appropriate circumstances such that the embodiments described herein are, for example, capable of operation in sequences other than those illustrated or otherwise described herein. Furthermore, the terms "include," and

“have,” and any variations thereof, are intended to cover a non-exclusive inclusion, such that a process, method, system, article, device, or apparatus that comprises a list of elements is not necessarily limited to those elements, but may include other elements not expressly listed or inherent to such process, method, system, article, device, or apparatus.

The terms “left,” “right,” “front,” “back,” “top,” “bottom,” “over,” “under,” and the like in the description and in the claims, if any, are used for descriptive purposes and not necessarily for describing permanent relative positions. It is to be understood that the terms so used are interchangeable under appropriate circumstances such that the embodiments of the invention described herein are, for example, capable of operation in other orientations than those illustrated or otherwise described herein.

The terms “couple,” “coupled,” “couples,” “coupling,” and the like should be broadly understood and refer to connecting two or more elements or signals, electrically, mechanically and/or otherwise. Two or more electrical elements may be electrically coupled but not be mechanically or otherwise coupled; two or more mechanical elements may be mechanically coupled, but not be electrically or otherwise coupled; two or more electrical elements may be mechanically coupled, but not be electrically or otherwise coupled. Coupling may be for any length of time, e.g., permanent or semi-permanent or only for an instant.

“Electrical coupling” and the like should be broadly understood and include coupling involving any electrical signal, whether a power signal, a data signal, and/or other types or combinations of electrical signals. “Mechanical coupling” and the like should be broadly understood and include mechanical coupling of all types.

The absence of the word “removably,” “removable,” and the like near the word “coupled” and the like does not mean that the coupling, etc. in question is or is not removable.

DETAILED DESCRIPTION OF EXAMPLES OF EMBODIMENTS

Some embodiments concern a method of distributing information regarding one or more electrical devices using a first server. Each of the one or more electrical devices can have unique identification information, an internal IP address, and an external IP address. The method can include: receiving in the first server a first request to register a first electrical device of the one or more electrical devices, the first request to register comprises the unique identification information, the internal IP address, and the external IP address of the first electrical device of the one or more electrical devices; storing in the first server the unique identification information, the internal IP address, and the external IP address of the first electrical device of the one or more electrical devices using the first server; receiving in the first server from a first client computer a first request for information regarding the first electrical device of the one or more electrical devices; using the first server to determine the external IP address of the first electrical device of the one or more electrical devices; redirecting the first request for the information to a first gateway device if an external IP address of the first client computer is identical to the external IP address of the first electrical device of the one or more electrical devices; and returning the external IP address of the first electrical device of the one or more electrical devices if the external IP address of the first client computer is different from the external IP address of the first electrical device of the one or more electrical devices

Various embodiments can concern a method of disseminating information regarding at least one electrical device using a registration server. The at least one electrical device has unique identification information, an internal IP address, and an external IP address wherein the external IP address is an IP address of a first gateway device for a first local network. The method can include: receiving in the registration server a first request to register the at least one electrical device, the first request to register includes the unique identification information, the internal IP address, and the external IP address of the at least one electrical device; storing in the registration server the unique identification information, the internal IP address, and the external IP address of the at least one electrical device using the registration server; receiving in the registration server from a first client computer a first request for information regarding the at least one electrical device, the first request includes the external IP address of the first client computer and the unique identification information of the at least one electrical device; providing to the first client computer the external IP address of the at least one electrical device if the external IP address of the first client computer is different from the external IP address of the at least one electrical device; and providing to the first client computer the internal IP address of the at least one electrical device if the external IP address of the first client computer is identical to the external IP address of the at least one electrical device. The registration server is not part of the first local network. In some examples, the at least one electrical device and the first gateway device are part of the first local network.

Many embodiments can concern a method of determining information regarding an electrical device. The electrical device having unique identification information, an internal IP address, and an external IP address. The method can include: requesting the internal IP address of the electrical device; receiving the internal IP address of the electrical device; setting-up the electrical device, wherein setting-up the electrical device can include communicating to a first server the unique identification information, the internal IP address and the external IP address of the electrical device; using the client computer to query the first server for at least one of the internal IP address or the external IP address of the electrical device; using the client computer to receive at least one of the internal IP address of the electrical device or the external IP address of the electrical device; using the client computer to access the electrical device using at least one of the internal IP address of the electrical device or the external IP address of the electrical device. The electrical device can be part of a different local network than the first server.

Yet other embodiments can concern a registration server configured to provide information regarding two or more electrical devices. Each of the two or more electrical devices has unique identification information, an internal IP address, and an external IP address. The registration server can include: (a) a registration module configured to receive at least two requests to register each of the two or more electrical devices, each of the at least two requests to register includes the unique identification information, the internal IP address, and the external IP address of the two or more electrical devices; (b) a storage module configured to store the unique identification information, the internal IP address, and the external IP address of each of the two or more electrical devices; (c) a request module configured to receive one or more requests for information regarding the two or more electrical devices from one or more client computers and further configured to determine an external IP address of

5

the one or more client computers making the one or more requests for the information; and (d) a return module. A first request of the one or more requests for the information is a request for the information about a first electrical device of the two or more electrical devices is by a first client computer of the one or more client computers. The return module can be configured to redirect the first request of the one or more requests for the information by the first client computer of the one or more client computer to a first gateway device if the external IP address of the first client computer of the one or more client computers is identical to the external IP address of the first electrical device of the two or more electrical devices. The return module can be further configured return the external IP address of the first electrical device of the two or more electrical devices if the external IP address of the first client computer of the one or more client computers is different from the external IP address of the first electrical device of the two or more electrical devices.

Turning to the drawings, FIG. 1 illustrates a block diagram of a system 100 configured to provide information regarding at least one electrical device 110, according to a first embodiment. System 100 is merely exemplary and is not limited to the embodiments presented herein. System 100 can be employed in many different embodiments or examples not specifically depicted or described herein.

In some embodiments, system 100 can include: (a) at least one electrical device 110; (b) at least one of an internal client computer 130 or an external client computer 131; (c) at least one gateway device 150; (d) at least one lookup server 170; and (e) at least one registration server 190. In some examples, lookup server 170 and registration server 190 can be combined into a single dual purpose server and can be called a lookup server, a registration server, or the like. In various examples, internal client computer 130, electrical device 110, and gateway device 150 are part of a local network 101. Lookup server 170, registration server 190, and external client computer 131 are not part of local network 101.

Not to be taken in a limiting sense, a simple example of a method of using system 100 to provide information about electrical device 110 includes electrical device 110 being assigned a new dynamically generated internal IP address by gateway device 150 (or another networking device). Electrical device 110 then registers unique identification information, the assigned internal IP address, and the external IP address of electrical device 110 (e.g., the IP address of gateway device 150) with registration server 190. In some examples, electrical device 110 registers the assigned external IP address of electrical device 110 without knowing the assigned external IP address. For example, registration server 190 can obtain the external IP address of electrical device 110 using source packet information contained in the register request.

In some examples, registration server 190 can be a trusted DHCP-DNS server (a type of domain name system server that allows an electrical device to register both the internal and the external IP addresses of the electrical device). In many examples, registration server 190 is available and residing in a network (i.e., not local network 101) that is visible by any client (e.g., internal client computer 130 and external client computer 131) that needs to access registration server 190 (e.g., the public internet). Electrical device 110, as part of the registration process with registration server 190, also can also provide other unique identification information such as authentication information (e.g., a username and a password) for electrical device 110, service or

6

type of service it provides, model number, MAC address, etc. Electrical device 110 can re-register this information as needed (e.g., when the internal IP address of electrical device 110 is updated dynamically).

After the registration process is complete, registration server 190 can receive a request for information regarding electrical device 110 from a requesting client computer (e.g., internal client computer 130 or external client computer 131). The request for information can include the MAC address of electrical device 110 (or any other unique identification information). Registration server 190 can examine the MAC address (or any other unique identification information) and apparent external source IP address of a requesting client computer to determine what information to provide in response to the request for information. In some examples, the requesting client computer is also required to provide authentication information (e.g., username/password) for security purposes.

In some examples, if: (a) the apparent external source IP address of the requesting client computer matches the external IP address of electrical device 110, and (b) the unique identification information and the authentication information provided by the requesting client computer matches with the unique identification information and the authentication information of electrical device 110, registration server 190 determines that the client computer is requesting access to the information about electrical device 110 from within the same network (i.e., local network 101) as electrical device 110. In this case, registration server 190 returns the most recently registered internal IP address for electrical device 110.

In other examples, registration server 190 does not provide the most recently registered internal IP address of electrical device 110. Rather, registration server 190 redirects the request for information to gateway device 150, and gateway device 150 can provide the internal IP address of electrical device 110. By providing the internal IP address to the requesting client computer, the requesting client computer (e.g., internal client computer 130) is able to directly access the services provided by electrical device 110.

If the apparent external IP address of the requesting client computer is different than the external IP address of electrical device 110 but the unique identification information and authentication information provide by the client computer matches the stored information, registration server 190 can return the most recently registered external IP address of electrical device 110 to the requesting client computer.

FIG. 2 illustrates a block diagram of electrical device 110, according to the first embodiment. Electrical device 110 is merely exemplary and is not limited to the embodiments presented herein. Electrical device 110 can be employed in many different embodiments or examples not specifically depicted or described herein.

In some examples, electrical device 110 can include: (a) a system bus 211; (b) a controller 212 coupled to system bus 211; (c) at least one network connector 213; (d) at least one network adapter 214 coupled to system bus 211 and network connector 213; (e) storage module 216 coupled to system bus 211; (f) one or more application specific devices 217; (g) an operations module 221; (h) a set-up module 222; and (i) a registration module 223. In these examples, electrical device 110 does not have a visual display or a visual user interface. In the same or different examples, the components of electrical device 110 can be coupled together without using system bus 211. In various embodiments, the architecture of controller 212 can be compliant with any of a variety of commercially distributed architectures.

Network connector **213** can be any type of network connector such as, for example, an ethernet connector, a universal serial bus (USB) connector, a serial port connector, a parallel port connector, and the like. In other examples, network connector **213** can include a wireless network adapter and an antenna. In many examples, electrical device **110** can be coupled to gateway device **150** (FIG. 1) using network connector **213**.

Application specific devices **217** can include any other devices and/or adapters that are required for electrical device **110** to perform its designed functions. For example, electrical device **110** can be a motion detection device, and application specific devices **217** can include the sensors needed to detect motion. In many examples, application specific devices **217** do not include any devices that have visual display capabilities (e.g., a monitor or a liquid crystal display (LCD)). In many examples, adding a visual display device is too costly or unnecessary for the primary function of electrical device **110**. Accordingly, when electrical device is configured using DHCP or another protocol, no mechanism exists to provide the configuration information (e.g., an internal or external IP address of electrical device **110**) to a user.

Storage module **216** can include memory, both read only memory (ROM) and random access memory (RAM). Non-volatile portions of storage module **216** or the ROM can be encoded with a boot code sequence suitable for restoring electrical device **110** (FIG. 1) to a functional state after a system reset. Storage module **216** can also include a hard disk and/or other types of storage devices.

Operations modules **221** can be configured to operate and provide the designed functionality of electrical device **110**. Set-up module **222** can be configured to handle the set-up and configuration of electrical device **110**. Registration module **223** can be configured to communicate with lookup server **170** (FIG. 1) and/or registration server **190** (FIG. 1) to register the internal and external IP addresses and other information about electrical device **110**.

In some examples, storage module **216** can store operations module **221**, set-up module **222**, and/or registration module **223**, and these modules can be performed using controller **212**. When electrical device **110** of FIGS. 1 and 2 is running, program instructions stored in storage module **216** can be executed by controller **212**. A portion of the program instructions stored in storage module **216** can be suitable for carrying out at least portions of the methods of transmitting data between other elements of system **100** (FIG. 1), as described hereinafter with respect to FIGS. 8-12. In same or different examples, at least portions of the methods of transmitting data between the other elements, as described hereinafter with respect to FIGS. 8-12, can be implemented by circuitry in electrical device **110**.

FIG. 3 illustrates a rear view of gateway device **150** for broadcasting data, according to the first embodiment. Gateway device **150** is merely exemplary and is not limited to the embodiments presented herein. Gateway device **150** can be employed in many different embodiments or examples not specifically depicted or described herein. In the same or different embodiments, gateway device **150** can be considered a computer component for communicating data between a network (e.g., the internet) and internal client computer **130** (FIG. 1) and electrical device **110** (FIG. 1). Gateway device **150** can be an electrical device used to connect a computer or electrical device to a network. For example, gateway device **150** can include one or more of: a router, a hub, a wireless access point, a modem-router, a

VoIP (voice over internet protocol) modem-router, a wireless ethernet bridge, and a wireless network interface card (WNIC).

Gateway device **150** can include a chassis **352** containing one or more circuit boards (not shown), one or more network connectors **351**, an input device **354**, and one or more antennas **355**. Antennas **355** can be used to transfer or transmit information using electromagnetic waves (i.e., a wireless network). Network connectors **351** can be any type of network connectors such as, for example, Ethernet connectors, universal serial bus (USB) connectors, serial port connectors, parallel port connectors, and the like. In one example, network connectors **351** include one ADSL (Asymmetric Digital Subscriber Line) connector and four Ethernet ports.

A representative block diagram of an example of the elements included in the circuit board(s) inside chassis **352** is shown in FIG. 4. In the embodiment shown in FIG. 4, a controller **456** is coupled to a system bus **457**. In various embodiments, the architecture of controller **456** can be compliant with any of a variety of commercially distributed architectures. In other examples, gateway device **150** (FIG. 3) does not include system bus **457**, and the components of gateway device **150** can communicate with system bus **457**.

In the embodiment of FIG. 4, system bus **457** is also coupled to storage module **458** that can include read only memory (ROM), random access memory (RAM), a hard drive and/or other storage devices. Also, various I/O (input/output) devices such as one or more network adapters **459** and **460**, an input adapter **461**, and other I/O devices and adapters **462** can be coupled to system bus **457**. Network adapter **459** can be coupled to antenna(s) **355**, and network adapter **460** can be coupled to network connectors **351**. Network connectors **351** and antenna(s) **355**, though network adapters **460** and **459**, respectively, can be coupled to controller **212** (FIG. 2) directly or through system bus **457**. In other embodiments, a single network adapter can be used to control all of these I/O devices.

In some examples, network adapter **459** can include transmitter **463** and receiver **464**. Transmitter **463** can be a radio frequency or other wireless transmitter. Receiver **464** can be a radio frequency or other wireless receiver. In numerous embodiments, transmitter **463** and receiver **464** can include or be radios.

When gateway device **150** in FIGS. 1 and 3-4 is running, program instructions stored in storage module **458** are executed by controller **456**. A portion of the program instructions stored in storage module **458** can be suitable for carrying out at least portions of the methods of transmitting data between other elements of system **100** (FIG. 1), as described hereinafter with respect to FIGS. 8-12. In same or different examples, at least portions of the methods of transmitting data between the other elements, as described hereinafter with respect to FIGS. 8-12, can be implemented by circuitry in gateway device **150**.

FIG. 5 illustrates a block diagram of internal client computer **130**, according to the first embodiment. Internal client computer **130** is merely exemplary and is not limited to the embodiments presented herein. Internal client computer **130** can be employed in many different embodiments or examples not specifically depicted or described herein. Internal client computer **130** includes a chassis **535** containing one or more circuit boards (not shown), a USB (universal serial bus) port **542**, a Compact Disc Read-Only Memory (CD-ROM) and/or Digital Video Disc (DVD) drive **532**, and a hard drive **534**.

A representative block diagram of the elements included on the circuit boards inside chassis **535** is shown in FIG. 6. A controller **640** in FIG. 6 is coupled to a system bus **644** in FIG. 6. In various embodiments, the architecture of controller **640** can be compliant with any of a variety of commercially distributed architecture families.

System bus **644** also is coupled to memory **638** that includes both read only memory (ROM) and random access memory (RAM). Non-volatile portions of memory **638** or the ROM can be encoded with a boot code sequence suitable for restoring internal client computer **130** (FIG. 1) to a functional state after a system reset. In addition, memory **638** can include microcode such as a Basic Input-Output System (BIOS).

In the depicted embodiment of FIGS. 5-6, various I/O devices such as a disk controller **634**, a graphics adapter **649**, a video controller **648**, a keyboard adapter **643**, a mouse adapter **647**, network adapter **646**, and other I/O devices and adapters **645** can be coupled to system bus **644**. Keyboard adapter **643** and mouse adapter **647** are coupled to keyboard **536** (FIGS. 5 and 6) and mouse **537** (FIGS. 5 and 6), respectively. While graphics adapter **649** and video controller **648** are indicated as distinct units in FIG. 6, video controller **648** can be integrated into graphics adapter **649**, or vice versa in other embodiments. Video controller **648** is suitable for refreshing monitor **538** (FIGS. 5 and 6) to display images in monitor **538** (FIGS. 5 and 6) of internal client computer **130**. Disk controller **634** can control hard drive **534** (FIGS. 5 and 6), CD-ROM or DVD drive **532** (FIGS. 5 and 6), and USB port **542** (FIGS. 5 and 6). In other embodiments, distinct units can be used to control each of these devices separately.

Network adapters **646** can be coupled to one or more antennas **631**. In some embodiments, network adapters **646** are part of a WNIC (wireless network interface controller) card **629** plugged or coupled to an expansion port (not shown) in internal client computer **130** (FIG. 1). In other embodiments, WNIC card **629** is a wireless network card built into internal client computer **130** (FIG. 1). A wireless network adapter can be built into internal client computer **130** by having wireless ethernet capabilities integrated into the motherboard chipset (not shown), or implemented via a dedicated wireless ethernet chip (not shown), connected through the PCI (peripheral component interconnector) or a PCI express bus. In some examples, each of network adapters **646** can include a transmitter **633** and receiver **635**. Transmitter **633** can be a radio frequency or other wireless transmitter. Receiver **635** can be a radio frequency or other wireless receiver. In numerous embodiments, transmitter **633** and receiver **635** can include or be radios. In other embodiments, network adapter **646** can be a wired network adapter.

When internal client computer **130** in FIGS. 1 and 5-6 is running, program instructions stored on a USB drive coupled to USB port **542**, on a CD-ROM or DVD in CD-ROM and/or DVD drive **532**, on hard drive **534**, or in memory **638** (FIG. 6) are executed by controller **640** (FIG. 6). A portion of the program instructions stored in these devices can be suitable for carrying out at least portions of the methods of transmitting data between a network (e.g., the internet) and internal client computer **130** and electrical device **110**, as described hereinafter with respect to FIGS. 5-8. In same or different examples, at least portions of the methods of transmitting data between a network and internal client computer **130** and electrical device **110**, as described hereinafter with respect to FIGS. 5-8, can be implemented by circuitry in internal client computer **130**.

In various embodiments, external client computer **131** can be similar to or the same as internal client computer **130**.

FIG. 7 illustrates a block diagram of an exemplary example of registration server **190**, according to the first embodiment. Registration server **190** is merely exemplary and is not limited to the embodiments presented herein. Registration server **190** can be employed in many different embodiments or examples not specifically depicted or described herein.

Registration server **190** can perform two main functions in some examples. The first function is to receive registration information provided by electrical device **110** (FIG. 1). When this information is received, registration server **190** stores the external IP address (or source IP address) of the requesting device (i.e., electrical device **110**, where the external IP address of electrical device **110** is the external IP address of gateway device **150**) provided by electrical device **110** and/or gateway device **150**, as well as the internal IP address of the same requesting device provided by electrical device **110** and/or gateway device **150**, and any other uniquely identifying information contained within the registration information. In some examples, electrical device **110** can provide its external IP address. In other examples, registration server **190** can determine the external IP address of electrical device **110** from header information of the TCP/IP packets from electrical device **110**.

The second function of registration server **190** is to serve as a type of DNS server. Traditional DNS servers merely provide a stored external IP address as a result of a look-up request with no other input. Registration server **190**, on the other hand, receives a MAC address (or any other unique identification information) from the requesting client computer (e.g., internal client computer **130** and/or external client computer **131**) and can examine the MAC address (or any other unique identification information) and the apparent external source IP address of the requesting client computer. This apparent external source IP address of the requesting client computer is used to determine the information about a registered electrical device (e.g., electrical device **110**) to return to the requesting computer. In some examples, the requesting client computer is also required to provide authentication information (e.g., a username and a password) for security purposes.

This approach can use external public DNS server mechanisms and can add the additional functionality of being able to register two IP addresses to a single DNS hostname entry. Registration server **190** can be configured to determine the proper IP address to return in response to a query.

Other systems and methods to return dynamically assigned IP addresses can introduce a second layer DNS server within a local network to allow discovery of dynamically assigned IP addresses. Using these other methods, in order to access a particular electrical device, the external client (e.g., a device outside the local network) needs to look up the local network address first, and then query the internal lookup server to determine the internal IP address of the specific electrical device. In contrast, the system and device described herein allows each electrical device within the local network to register itself (or allows for a third device like a gateway device to register the electrical device) to an external lookup server. Accordingly, the systems and methods described herein allow a single lookup to find the IP address(es) of electrical device **110**.

Furthermore, in these other systems and methods that use a second layer DNS server, all of the nodes (i.e., internal client computers, electrical devices, etc.) inside the network have to point their primary DNS server records to the

11

internal DNS server of the local network for the systems or methods to work. If that internal DNS server disappeared for whatever reason (e.g., crashed, turned off, etc.), all of the internal nodes on the local network would also fail because these other devices would lack the ability to resolve domain names. In contrast, the systems and methods described herein do not require reworking the internal configuration of the local network or relying on a public system that is more robust.

Referring again to FIG. 7, in many examples, registration server **190** (i.e., a serving device) can be configured to provide information regarding one or more electrical devices (e.g., an internal IP address, and/or an external IP address). Registration server **190** can include: (a) at least one input device **754**; (b) at least one input adapter **761**; (c) at least one network adapter **760**; (d) at least one network connector **751**; (e) at least one controller **756**; (f) other I/O devices and adapters **762**; (g) a storage module **758**; (h) a security module **771** configured to run on controller **756**; (i) a registration module **772** configured to run on controller **756**; (j) a request module **773** configured to run on controller **756**; and (k) a return module **774** configured to run on controller **756**.

Security module **771** can be configured to determine if authentication information is correct. In various embodiments, security module **771** can determine if the authentication information provided by the client computer matches the stored authentication information for electrical device **110**. For example, security module **771** can authenticate the user based on the username and the password. That is, security module **771** can authenticate the user if the username and the password of the authentication information provided by the client computer is the same as the username and the password for electrical device **110** as stored by the registration server

Registration module **772** can be configured to receive at least one request to register the one or more electrical devices (e.g., electrical device **110**). In some examples, the request to register an electrical device can include at least one request to register the MAC address (or any other unique identification information), the internal IP address, and the external IP address of the electrical device. Storage module **758** can be configured to store the MAC address (or any other unique identification information), the internal IP address, and the external IP address of the one or more electrical devices. In the same or different examples, the request to register can also include authentication information.

Request module **773** can be configured to receive one or more requests for information regarding the one or more electrical devices from one or more client computers. Request module **773** can be further configured to determine the external IP address of the requesting client computer. For example, request module **773** can determine the external IP address of the requesting client computer by examining the headers of the TCP/IP packets from the requesting client computer.

Return module **774** can be configured return the external IP address of electrical device **110** if the external IP address of the client computer (e.g., external client computer **131**) is different than the external IP address of electrical device **110**. Furthermore, return module **774** can be configured to redirect a request for information about electrical device **110** to gateway device **150** if an external IP address of the first client computer (i.e., internal client computer **130**) is the same as the external IP address of electrical device **110**. In other examples, return module **774** can return the informa-

12

tion about electrical device **110** regardless of the external IP address of the requesting client computer.

"Server," as used herein, can refer to a single computer, a single server, or a cluster or collection of servers. Typically, a cluster or collection of servers can be used when the demands by client computers (e.g., electrical device **110**, internal client computer **130**, and/or external client computer **131**) are beyond the reasonable capability of a single server or computer. In many embodiments, the servers in the cluster or collection of servers are interchangeable from the perspective of the client computers and can be located at the same or different places. Furthermore, the server can have internal and/or external memory.

If registration server **190** is a single server, it can include registration module **772**, request module **773**, and return module **774**. In other examples, a first server can include a first portion of these modules, and one or more second servers can include a second, possibly overlapping, portion of these modules. In these examples, registration server **190** can comprise the combination of the first server and the one or more second servers.

In some examples, storage module **758** can store the information about the one or more electrical devices. In some examples, storage module can store a structured collection of records or data, for instance. For example, the information about the one or more electrical devices can be stored as an XML (Extensible Markup Language) database, MySQL database, or an Oracle® database. In the same or different embodiments, the information about the one or more electrical devices can be stored in a searchable group of individual data files.

Turning to another embodiment, FIG. 8 illustrates a flow chart for an exemplary embodiment of a method **800** of distributing information regarding one or more electrical devices using a first server. Method **800** can also be considered a method of determining information regarding at least one electrical device. Method **800** is merely exemplary and is not limited to the embodiments presented herein. Method **800** can be employed in many different embodiments or examples not specifically depicted or described herein. In some embodiments, the activities, the procedures, and/or the processes of method **800** can be performed in the order presented. In other embodiments, the activities, the procedures, and/or the processes of method **800** can be performed in any other suitable order. In still other embodiments, one or more of the activities, the procedures, and/or the processes in method **800** can be combined or skipped.

Referring to FIG. 8, method **800** includes an activity **810** of providing authentication information for an electrical device. In some examples, the authentication information is provided to a user of the electrical device. In some examples, the electrical device can be similar to or the same as electrical device **110** of FIG. 1. The authentication information can include at least one of a username or a password.

In some embodiments, a user of an electrical device can receive the authentication information with the electrical device. For example, the authentication information can be included with the packaging of the electrical device. In another example, a user of the electrical device can request the information (e.g., request the information over a website of the manufacturer or distributor of the electrical device) and the manufacturer or distributor, for example, can provide the authentication information. In still another example, the electrical device can be used to create at least one of the username or the password. In yet another example, the electrical device can provide the predetermined authentication information to the user.

13

Method **800** in FIG. **8** continues with an activity **815** of setting-up the electrical device. In various embodiments, setting-up the electrical device can include coupling the electrical device to a gateway device and performing any necessary set-up routines that are specific to the electrical device. After being coupled to the gateway device, the electrical device can request from the gateway device (or another networking device) an assignment of an internal IP address. For example, the assigning of an internal IP address can be performed using DHCP. In some examples, a set-up module (e.g., set-up module **222** (FIG. **2**)) can be used to help facilitate the set-up of the electrical device.

After the set-up process is complete, in some examples, the electrical device will have been assigned an internal IP address, but a user of the electrical device will lack an easy method to determine the new IP address if the electrical device lacks a visual user interface. The rest of method **800** provides an easy method for a user to determine the new IP address of the electrical device without having to navigate proprietary menus or screens in a computer, the electrical device, or the gateway device.

Subsequently, method **800** of FIG. **8** includes an activity **820** of registering the electrical device. In some example, information about the electrical device can be registered with a registration server. For example, the electrical device and the registration server can be similar to or the same as electrical device **110** and registration server **190** of FIG. **1**. FIG. **9** illustrates a flow chart for an exemplary embodiment of activity **820** of registering the electrical device, according to the first embodiment.

Referring to FIG. **9**, activity **820** includes a procedure **905** of communicating the request to register the electrical device to a registration server. In many examples, the electrical device can communicate the request to register the electrical device to the registration server via the Internet or another communications network. In some examples, the electrical device can include its MAC address, its internal IP address, its external IP address, and/or other unique identification information as part of the request for registration. In some examples, the electrical device automatically communicates this information to the registration server in real time. In the same or different examples, the request for registration can also include the authentication information associated with the electrical device.

Activity **820** in FIG. **9** continues with a procedure **915** of receiving the request to register the electrical device. In some examples, the registration server can receive the request to register from the electrical device. The received request for registration can include the MAC address, the internal IP address, the external IP address, and/or other unique identification information of the first electrical device. In other examples, the request to register includes the MAC address and the internal IP address, but not the external IP address. In these examples, the registration server can determine the external IP address by examining the header or other information transferred as part of the standard TCP/IP packet. In the same or different examples, the request for registration can also include the authentication information associated with the electrical device. In some examples, a registration module (e.g., registration module **772** of FIG. **7**) can handle at least part of procedure **915**.

Subsequently, activity **820** of FIG. **9** includes a procedure **925** of processing the request to register the electrical device. In some embodiments, procedure **925** can include storing the MAC address, the internal IP address, the external IP address, and/or other unique identification informa-

14

tion of the electrical device. In the same or different examples, the registration server can also store the authentication information associated with the electrical device. For example, the registration server can store the registration information of the electrical device in a storage module. In various examples, the storage module can be similar to or the same as storage module **758** of FIG. **7**. In some examples, a registration module (e.g., registration module **772** of FIG. **7**) can handle at least part of procedure **925**. After procedure **925**, activity **820** is complete.

In various embodiments, activity **820** can be repeated to register different electrical devices. For example, activity **820** can be performed to register a first electrical device and repeated one or more second times to register one or more second electrical devices.

Referring again to FIG. **8**, method **800** of FIG. **8** continues with an activity **825** of determining the address of registration server. In some examples, a client computer (e.g., internal client computer **130** or external client computer **131** of FIG. **1**) can desire to request information about an electrical device registered with the registration server, but the client computer needs the IP address of the registration server. In activity **825**, the client computer can determine the IP address of the registration server by sending a request to a lookup server for the IP address of the registration server. The lookup server can return the IP address of the registration server to the client computer. In various examples, the client computer can send a DNS (domain name server) lookup request to the lookup server to retrieve the IP address of the registration server. In many embodiments, the lookup server can be similar or identical to lookup server **170** of FIG. **1**.

After determining the IP address of the registration server, method **800** in FIG. **8** continues with an activity **830** of communicating a request for information about the electrical device. In many embodiments, a client computer (e.g., internal client computer **130** or external client computer **131** of FIG. **1**) can query the registration server for at least one of the internal IP address or the external IP address of the electrical device. In some examples, the client computer can transmit the request for information about the electrical device to the registration server over the Internet and/or one or more other networks. In some examples, the request for information can include the MAC address or other unique identification information of the electrical device.

Subsequently, method **800** of FIG. **8** includes an activity **835** of processing a request for information about the electrical device. FIG. **10** illustrates a flow chart for an exemplary embodiment of activity **835** of processing a request for information about the electrical device, according to the first embodiment.

Referring to FIG. **10**, activity **835** includes a procedure **1060** of determining if the electrical device is registered. In some examples, the registration server can determine whether the electrical device is registered by searching the stored information about registered electrical devices to determine if the specific electrical device is registered with the registration server. In various embodiments, the request module of the registration server can determine if any information exists in the storage module for the MAC address or other unique identification information of the electrical device. In some examples, a request module (e.g., request module **773** of FIG. **7**) can perform at least part of procedure **1060**. If the electrical device is not registered with the registration server, the next procedure in activity **835** in FIG. **10** is a procedure **1061**. If the electrical device is

15

registered with the registration server, the next procedure in activity **835** in FIG. **10** is a procedure **1062**.

Procedure **1061** communicates to the client computer that no such electrical device is registered. If the request module determines that the electrical device for which information was requested is not registered with the registration server, the return module can communicate to the client computer that no information is available about the specific electrical device. In some examples, a return module (e.g., return module **774** of FIG. **7**) can perform at least part of procedure **1061**. If no such electrical device is registered after procedure **1061**, activity **835** (FIGS. **8** and **10**) and method **800** (FIG. **8**) are complete.

Procedure **1062** authenticates the client computer. In some examples, to provide enhanced security, authentication of the client computer can be required before information about the electrical device is provided to the user of the client computer. FIG. **11** illustrates a flow chart for an exemplary embodiment of procedure **1062** of authenticating the client computer, according to the first embodiment. In some examples, a security module (e.g., security module **771** of FIG. **7**) can perform at least part of procedure **1062**.

Referring to FIG. **11**, procedure **1062** includes a process **1171** of requesting authentication information from the client computer. In some examples, the requested authentication information can include at least one of a username or a password.

Next, procedure **1062** of FIG. **11** includes a process **1172** of communicating authentication information to the first server. In some examples, the client computer can provide at least one of a username or a password to the registration server.

Procedure **1062** in FIG. **11** continues with a process **1173** of receiving authentication information of a user of the client computer. In some examples, the requesting module or the return module of the registration server can receive the authentication information from the client computer.

Subsequently, procedure **1062** of FIG. **11** includes a process **1174** of determining if authentication information is correct. In various embodiments, the security module of the registration server can determine if the authentication information provided by the client computer matches the stored authentication information for the electrical device. For example, the security module can authenticate the user based on the username and the password. That is, the registration server can authenticate the user if the username and the password of the authentication information provided by the client computer is the same as the username and the password for the electrical device as stored by the registration server. If the authentication information is correct, procedure **1062** is complete and the next procedure is procedure **1063** of FIG. **10**. If the authentication information is not correct, the next process in procedure **1062** of FIG. **11** is process **1175**.

Process **1175** informs the user that the authentication information is not correct. In some examples, the registration server can communicate to the client computer that the authentication information is not correct and that the registration server cannot process the request for information about the electrical device. In some embodiments, the registration server can give the user one or more additional attempts to submit the correct authentication information before rejecting the request. After process **1175**, procedure **1062**, activity **835** (FIGS. **8** and **10**), and method **800** (FIG. **8**) are complete.

In other embodiments, the registration server does not require authentication of the user of the client computer before providing the information about the electrical device.

16

In these examples, procedure **1062** of FIG. **10** can be skipped.

Referring again to FIG. **10**, activity **835** includes a procedure **1063** of providing the requested information about the electrical device. FIG. **12** illustrates a flow chart for an exemplary embodiment of procedure **1063** of providing the requested information about the electrical device, according to the first embodiment. In some examples, a return module (e.g., return module **774** of FIG. **7**) can perform at least part of procedure **1063**.

Referring to FIG. **12**, procedure **1063** includes a process **1271** of determining if the client computer and the electrical device are in the same local network. Depending on whether the client computer and the electrical device are in the same internal network, different information may be provided to the client computer and may be provided by a different entity (e.g., registration server **190** or gateway device **150**). In some examples, the external IP address of the client computer and the electrical device can be compared to determine if the client computer and the electrical device are in the same local network. In other embodiments, other mechanism can be used to determine if the client computer and the electrical device are in the same local network.

If the external IP addresses are the same, the registration server can conclude that the client computer and the electrical device are in the same local network, and the next process in procedure **1063** of FIG. **12** is process **1273**. If the external IP addresses of the electrical device and the client computer are different, the next process in procedure **1063** of FIG. **12** is process **1272**.

Process **1272** provides the registration information. In some examples, if the client computer and the electrical device are not in the same local network, the registration server can return the external IP address of the electrical device (e.g., electrical device **110**) to the client computer (e.g., external client computer **131**). After providing the registration information in process **1272**, procedure **1063** and activity **835** (FIGS. **8** and **10**) are complete.

Process **1273** redirects the request for the information about the electrical device to the gateway device. In many examples, the registration server can redirect a request for the information about the electrical device to a gateway device if an external IP address of the client computer is the same as the external IP address of the electrical device. The gateway device can then provide the internal IP address. In other embodiments, the registration server can provide the information and process **1273** is unnecessary.

Subsequently, procedure **1063** of FIG. **12** includes a process **1274** of providing the registration information. In some examples, if the client computer and the electrical device are in the same internal network, the gateway device can return the internal IP address of the electrical device to the client computer (e.g., internal client computer **130**). After process **1274**, procedure **1063** and activity **835** (FIGS. **8** and **10**) are complete.

Referring back to FIG. **8**, method **800** continues with an activity **840** of accessing the electrical device from a client computer. In some examples, the client computer can use at least one of the internal IP address or the external IP address of the electrical device to access the electrical device.

Although the invention has been described with reference to specific embodiments, it will be understood by those skilled in the art that various changes may be made without departing from the spirit or scope of the invention. Accordingly, the disclosure of embodiments of the invention is intended to be illustrative of the scope of the invention and

17

is not intended to be limiting. It is intended that the scope of the invention shall be limited only to the extent required by the appended claims. For example, activities **810**, **815**, **820**, **825**, **830**, **835** and **840** of FIG. 8, procedures **905**, **915**, and **925** of FIG. 9, procedures **1060**, **1061**, **1062**, and **1063**, processes **1171**, **1172**, **1173**, **1174**, and **1175**, and processes **1271**, **1272**, **1273**, and **1274** may be comprised of many different activities and procedures and be performed by many different modules, in many different orders, that any element of FIG. 1 may be modified, and that the foregoing discussion of certain of these embodiments does not necessarily represent a complete description of all possible embodiments.

All elements claimed in any particular claim are essential to the embodiment claimed in that particular claim. Consequently, replacement of one or more claimed elements constitutes reconstruction and not repair. Additionally, benefits, other advantages, and solutions to problems have been described with regard to specific embodiments. The benefits, advantages, solutions to problems, and any element or elements that may cause any benefit, advantage, or solution to occur or become more pronounced, however, are not to be construed as critical, required, or essential features or elements of any or all of the claims, unless such benefits, advantages, solutions, or elements are stated in such claim.

Moreover, embodiments and limitations disclosed herein are not dedicated to the public under the doctrine of dedication if the embodiments and/or limitations: (1) are not expressly claimed in the claims; and (2) are or are potentially equivalents of express elements and/or limitations in the claims under the doctrine of equivalents.

What is claimed is:

1. A method of disseminating information regarding at least one electrical device using a registration server, the at least one electrical device has unique identification information, an internal IP address, and an external IP address, wherein the external IP address of the at least one electrical device is an IP address of a first gateway device for a first local network comprising the at least one electrical device and the first gateway device, the method comprising:

receiving in the registration server a first request to register the at least one electrical device, the first request to register includes the unique identification information, the internal IP address, and the external IP address of the at least one electrical device;

storing in the registration server the unique identification information, the internal IP address, and the external IP address of the at least one electrical device;

receiving in the registration server from a first client computer a first request for the information regarding the at least one electrical device, the first request for the information includes the external IP address of the first client computer and the unique identification information of the at least one electrical device;

requesting first authentication information from the first client computer;

authenticating the first client computer based on the first authentication information;

providing to the first client computer the external IP address of the at least one electrical device if the external IP address of the first client computer is different from the external IP address of the at least one electrical device; and

providing to the first client computer the internal IP address of the at least one electrical device if the

18

external IP address of the first client computer is identical to the external IP address of the at least one electrical device,

wherein:

the registration server is not part of the first local network; receiving in the registration server the first request to register the at least one electrical device further comprises:

receiving second authentication information from the at least one electrical device;

the first authentication information comprises a first username and a first password;

the second authentication information comprises a second username and a second password; and

authenticating the first client computer comprises:

authenticating the first client computer if the first username and the first password are identical to the second username and the second password.

2. The method of claim 1, wherein:

providing to the first client computer the internal IP address of the at least one electrical device comprises: redirecting the first request for the information to the first gateway device if the external IP address of the first client computer is identical to the external IP address of the at least one electrical device.

3. The method of claim 1, further comprising:

providing the second authentication information to a user of the at least one electrical device.

4. A method of determining information regarding an electrical device, the electrical device having unique identification information, an internal IP address, and an external IP address, the method comprising:

using a client computer to query a first server for at least one of the internal IP address or the external IP address of the electrical device;

receiving at the client computer a request for first authentication information from the first server, the first authentication information comprises a first username and a first password;

sending the first authentication information to the first server from the client computer to allow the first server to authenticate the client computer if the first username and the first password are identical to a second username and a second password, the electrical device having been registered in the first server using second authentication information comprising the second username and the second password;

using the client computer to receive at least one of the internal IP address of the electrical device or the external IP address of the electrical device;

using the client computer to access the electrical device using at least one of the internal IP address of the electrical device or the external IP address of the electrical device,

wherein:

the electrical device is part of a different local network than the first server.

5. The method of claim 4, further comprising:

coupling the electrical device to a gateway device before communicating to the first server.

6. The method of claim 4, wherein:

the electrical device is devoid of a visual user interface.

7. A registration server configured to provide information regarding two or more electrical devices, each of the two or more electrical devices has unique identification information, an internal IP address, and an external IP address, the registration server comprising:

19

a registration module configured to receive at least two requests to register each of the two or more electrical devices, each of the at least two requests to register includes the unique identification information, the internal IP address, and the external IP address of the two or more electrical devices;

a storage module configured to store the unique identification information, the internal IP address, and the external IP address of each of the two or more electrical devices;

a request module configured to receive one or more requests for information regarding the two or more electrical devices from one or more client computers and further configured to determine an external IP address of the one or more client computers making the one or more requests for the information;

a security module; and

a return module,

wherein:

a first request of the one or more requests for the information is a request for the information about a first electrical device of the two or more electrical devices is by a first client computer of the one or more client computers;

at least one of the at least two requests to register each of the two or more electrical devices comprises second authentication information from the first electrical device of the two or more electrical devices;

the second authentication information comprises a second username and a second password;

the security module is configured to request first authentication information from the first client computer of the one or more client computers;

the first authentication information comprises a first username and a first password;

the security module is configured to authenticate the first client computer based on the first authentication information if the first username and the first password are identical to the second username and the second password;

the return module is configured to redirect the first request of the one or more requests for the information by the first client computer of the one or more client computers to a first gateway device if the external IP address of the first client computer of the one or more client computers is identical to the external IP address of the first electrical device of the two or more electrical devices; and

the return module is further configured return the external IP address of the first electrical device of the two or more electrical devices if the external IP address of the first client computer of the one or more client computers is different from the external IP address of the first electrical device of the two or more electrical devices.

8. The registration server of claim 7, wherein:
none of the two or more electrical devices has a visual user interface.

9. A method of distributing information regarding at least one electrical device using a first server, each of the at least one electrical device has unique identification information, an internal IP address, and an external IP address, wherein the external IP address of the at least one electrical device is an IP address of a first gateway device for a first local network comprising the at least one electrical device and the first gateway device, the method comprising:

receiving from the at least one electrical device a first request to register the at least one electrical device, the

20

first request to register includes the unique identification information, the internal IP address, and the external IP address of the at least one electrical device;

using the first server to register the at least one electrical device;

receiving in the first server from a first client computer a first request for information regarding the at least one electrical device, the first request for the information includes the external IP address of the first client computer and the unique identification information of the at least one electrical device;

requesting first authentication information from the first client computer;

authenticating the first client computer based on the first authentication information;

providing to the first client computer the external IP address of the at least one electrical device if the external IP address of the first client computer is different from the external IP address of the at least one electrical device; and

redirecting the first request for the information to the first gateway device if the external IP address of the first client computer is identical to the external IP address of the at least one electrical device,

wherein:

the first server is not part of the first local network;

receiving from the at least one electrical device the first request to register the at least one electrical device comprises:

receiving second authentication information from the at least one electrical device;

the first authentication information comprises a first username and a first password;

the second authentication information comprises a second username and a second password; and

authenticating the first client computer comprises:

authenticating the first client computer if the first username and the first password are identical to the second username and the second password.

10. The method of claim 9, wherein:

the first gateway device and the at least one electrical device are not using an UPnP (universal plug and play) standard or a DLNA (digital living network alliance) standard; and

the first gateway device and the at least one electrical device are not using a Bonjour protocol.

11. The method of claim 9, further comprising:

providing the second authentication information to a user of the at least one electrical device.

12. A method of distributing information regarding one or more electrical devices using a first server, each of the one or more electrical devices has unique identification information, an internal IP address, and an external IP address, the method comprising:

registering in the first server a first electrical device of the one or more electrical devices using first information, the first information comprises the unique identification information, the internal IP address, and the external IP address of the first electrical device of the one or more electrical devices;

receiving in the first server from a first client computer a first request for information regarding the first electrical device of the one or more electrical devices;

requesting first authentication information from the first client computer;

authenticating the first client computer based on the first authentication information;

21

using the first server to determine the external IP address of the first electrical device of the one or more electrical devices;

redirecting the first request for the information to a first gateway device if an external IP address of the first client computer is identical to the external IP address of the first electrical device of the one or more electrical devices; and

returning the external IP address of the first electrical device of the one or more electrical devices if the external IP address of the first client computer is different from the external IP address of the first electrical device of the one or more electrical devices, wherein:

the first electrical device of the one or more electrical devices is part of a different local network than the first server;

the first gateway device and the first electrical device of the one or more electrical devices are not using an UPnP (universal plug and play) standard and a DLNA (digital living network alliance) standard; and

the first gateway device and the first electrical device of the one or more electrical devices are not using a Bonjour protocol;

registering in the first server the first electrical device of the one or more electrical devices using the first information further comprises:

receiving second authentication information from the first electrical device of the one or more electrical devices; the first authentication information comprises a first username and a first password;

the second authentication information comprises a second username and a second password; and

authenticating the first client computer comprises:

authenticating the first client computer if the first username and the first password are identical to the second username and the second password.

13. The method of claim 12, wherein:

the first electrical device of the one or more electrical devices is devoid of a visual user interface.

14. The method of claim 12, further comprising:

receiving in the first server from the first client computer a second request for second information regarding a second electrical device of the one or more electrical devices;

using the first server to determine an external IP address of the second electrical device of the one or more electrical devices;

redirecting the second request for the second information to the first gateway device if the external IP address of the first client computer is identical to the external IP address of the second electrical device of the one or more electrical devices; and

returning the external IP address of the second electrical device of the one or more electrical devices if the external IP address of the first client computer is different from the external IP address of the second electrical device of the one or more electrical devices.

15. The method of claim 12, further comprising:

receiving a request for an IP address of the first server from the first client computer; and

providing the IP address of the first server to the first client computer.

16. A method of distributing information regarding an electrical device using a first server, the electrical device

22

having unique identification information, an internal IP address, and an external IP address, the method comprising:

receiving first information at the first server from the electrical device, the first information comprising the unique identification information, the internal IP address, and the external IP address of the electrical device;

registering in the first server the electrical device using the unique identification information;

receiving in the first server from a client computer a first query for at least one of the internal IP address or the external IP address of the electrical device;

requesting first authentication information from the client computer;

authenticating the client computer based on the first authentication information;

using the first server to determine the external IP address of the electrical device;

returning the external IP address of the electrical device if the external IP address of the client computer is different from the external IP address of the electrical device;

redirecting the first query to a first gateway device if an external IP address of the client computer is identical to the external IP address of the electrical device;

providing the client computer at least one of the internal IP address of the electrical device or the external IP address of the electrical device to allow the client computer to access the electrical device using at least one of the internal IP address of the electrical device or the external IP address of the electrical device,

wherein:

a local network comprises the first gateway device and the electrical device;

the electrical device communicates to the first server via the first gateway device;

the first server is not part of the local network;

the first gateway device and the electrical device are not using a UPnP (universal plug and play) standard or a DLNA (digital living network alliance) standard;

the first gateway device and the electrical device are not using a Bonjour protocol;

receiving the first information at the first server further comprises:

receiving second authentication information from the electrical device;

the first authentication information comprises a first username and a first password;

the second authentication information comprises a second username and a second password; and

authenticating the client computer comprises:

authenticating the client computer if the first username and the first password are identical to the second username and the second password.

17. The method of claim 16, wherein:

the first information is received at the first server based on automatic communication from the electrical device of the unique identification information, the internal IP address, and the external IP address of the electrical device.

18. The method of claim 17, wherein:

the electrical device is coupled to the first gateway device before using the electrical device to communicate to the first server.
